(54) Title: CONSTITUTIVE AND INDUCIBLE EPIDERMAL VECTOR SYSTEMS**(57) Abstract**

A loricrin constitutive vector for efficient expression of a nucleic acid sequence in epidermal cells comprising the 5' flanking region of the loricrin gene, said flanking region containing a TATA box, a cap site and a first intron and intron/exon boundary all in appropriate sequential and positional relationship for expression of a nucleic acid cassette, a 3' flanking sequence of the loricrin gene and a linker containing a unique restriction endonuclease site at the location of the start and stop codon. Said linker connecting the 5' flanking region to the 3' flanking sequence and said linker further providing a position for inserting the cassette. The cassette contains the specific nucleic acid sequence to be expressed. Also, there is a keratin K6 inducible vector for regulating expression of a nucleic acid sequence in epidermal cells comprising the 5' flanking region of the keratin K6 gene, said flanking region including the TATA box, a cap site and the first intron and intron/exon boundary all in sequential and positional relationship for expression of a nucleic acid cassette, a 3' flanking sequence of the keratin K6 gene, and a polylinker having a plurality of restriction endonuclease sites. The polylinker connects the 5' flanking region to the 3' flanking sequence and further provides a position for insertion of the cassette. The keratin K6 and loricrin vectors can be further regulated by the addition of a Vitamin D regulatory element. The vectors can be used in a bioreactor for generating a variety of products including proteins, polypeptides or antisense RNAs. The vectors can also be used for gene therapy in treatment of a variety of diseases in animals and humans including wound healing, surgical incisions, skin ulcers, psoriasis and skin cancer, and in vaccination.

-1-

CONSTITUTIVE AND INDUCIBLE EPIDERMAL VECTOR SYSTEMS

10 The invention was partially supported by a grant from the United States government under AR40240 awarded by the National Institutes of Health. The government has certain rights in this invention.

FIELD OF THE INVENTION

15 The present invention relates generally to expression vectors for use in expressing proteins and polypeptides in epidermal cells. More particularly it relates to a constitutive vector consisting of the loricrin gene promoter, its 5' flanking region, its 5' transcribed but untranslated region, its intron, its 3' transcribed but untranslated region, its contiguous non-coding DNA containing the gene's natural transcriptional termination region and its 3' flanking region. It further relates to an
20 inducible vector consisting of the K6 keratin gene promoter, its 5' flanking region, its 5' transcribed but untranslated region, its first intron, its 3' transcribed but untranslated region, its contiguous non-coding DNA containing the gene's natural transcriptional termination region and its 3' flanking region. Additionally it relates to the treatment of disease
25 using the constitutive and inducible vectors.

BACKGROUND OF THE INVENTION

30 The skin is the largest organ in the human body and, due to its accessibility, it is an attractive target for gene therapy. The outer layer of the skin is called the epidermis, and it is particularly attractive since epidermal cells can be grown *in vitro* from normal and affected patients,

are easily transformed genetically by vectors, and can be readily reintroduced by autografting. Previous studies investigating the feasibility of using epidermal cells for gene therapy have only considered this *ex vivo* approach. These investigations utilized retroviral vectors and their 5 promoters to introduce and express foreign genetic material in epidermal cells. Even though the epidermis is avascular, these studies demonstrated that proteins expressed in the epidermis were able to traverse the epidermal-dermal barrier and achieve systemic distribution (Morgan et al., Science, Vol. 237, pp. 1476-1479, (1987); Fenjves et al., PNAS USA, Vol. 10 86, pp. 8803-8807, (1989); Garlick et al., J. Invest. Dermatol., Vol. 97, pp. 824-829, (1991)). The accessibility of the epidermis makes it suitable for other routes of vector delivery that do not require an *ex vivo* approach, e.g., a gene gun (Sanford et al., Techniques, Vol. 3, pp. 3-16, (1991); Williams et al., PNAS USA, Vol. 88, pp. 2726-2730, (1991); Johnstone et 15 al., In Vitro Cell Dev. Biol., Vol. 27, pp. 11-14, (1991)). In addition, novel vector systems derived from genes normally expressed at high levels in epidermal cells, could prove optimal for achieving efficient, as well as regulated, expression of exogenous DNA. These vector systems are the subject of this invention.

20 The epidermis is a continuously regenerating stratified squamous epithelium. Differentiated epidermal cells are the progeny of proliferative cells located in the basal cell layer and there is substantial evidence suggesting that the regeneration process occurs in proliferative units composed of slowly cycling, self-renewing stem cells, proliferative but non-renewing transit amplifying cells, and post-mitotic maturing epidermal 25 cells (Iversen, et al., Cell Tissue Kinet., Vol. 1, pp. 351-367, (1968); MacKenzie, et al., Nature, Vol. 226, pp. 653-655, (1970); Christophers, et al., J. Invest. Dermatol., Vol. 56, pp. 165-170, (1971); Potten, In Stem Cells: Their Identification and Characterization, pp. 200-232, (1983); 30 Cotsarelis, et al., Cell, Vol. 61, pp. 1329-1337, (1990)). The maturation

-3-

process (terminal differentiation) is initiated when epidermal cells withdraw from the cell cycle and migrate from the basal layer into the spinous layer. Maturation continues as spinous cells migrate into the granular layer and terminates with the formation of the stratum corneum.

5 Morphological and biochemical studies have shown that terminal differentiation occurs in stages. (Matoltsy, J. Invest. Dermatol., Vol. 65, pp. 127-142, (1975)). Keratins K5 and K14 are major products of basal epidermal cells (Woodcock-Mitchell, et al., J. Cell Biol., Vol. 95, pp. 580-588, (1982)). These proteins assemble into 10 nm filaments (intermediate

10 filaments [IF]) and, together with microtubules (tubulin) and microfilaments (actin), comprise the cytoskeleton of epidermal cells (Steinert, P.M., et al., Cell, Vol. 42, pp. 411-419, (1985)). One of the earliest changes associated with the commitment to differentiation and migration into the spinous layer is the induction of another

15 differentiation-specific pair of keratins (K1 and K10). IF containing K1 and K10 replace those containing K5 and K14 as the major products of cells in the spinous layer (Woodcock-Mitchell, et al., J. Cell Biol., Vol. 95, pp. 580-588, (1982); Roop, et al., Proc. Natl. Acad. Sci., USA, Vol. 80, pp. 716-720, (1983); Schweizer, et al., Cell, Vol. 37, pp. 159-170, (1984)). The keratin IF formed by these proteins assemble into bundles. In the granular layer, another high molecular weight non-IF protein is synthesized, which is processed into filaggrin, and is thought to promote keratin filament aggregation and disulfide-bond formation (Dale, B.A., et al., Nature, Vol. 276, pp. 729-731, (1978); Harding, C.R., et al., J. Mol. Biol., Vol. 170, pp. 651-673, (1983)). In the final stage of epidermal cell maturation, transglutaminase catalyzes the crosslinking of involucrin and loricrin, by the formation of (γ -glutamyl) lysine isopeptides, into a highly insoluble cornified envelope which is located just beneath the plasma membrane (Rice and Green, Cell, Vol. 11, pp. 417-422, (1977); Mehrel, et al., Cell, Vol. 61, pp. 1103-1112, (1990)).

Genes or cDNAs encoding the major keratins expressed in epidermal cells have now been cloned: K5 (Lersch, et al., Mol. and Cell Biol., Vol. 8, pp. 486-493, (1988), K14 (Marchuk, et al., Proc. Natl. Acad. Sci, USA, Vol. 82, pp. 1609-1613, (1985); Knapp, et al., J. Biol. Chem., Vol. 262, pp. 938-945, (1987); Roop, et al., Cancer Res., Vol. 48, pp. 3245-3252, (1988), K1 (Steinert, et al., J. Biol. Chem., Vol. 260, pp. 7142-7149, (1985) and K10 (Krieg, et al., J. Biol. Chem., Vol. 260, pp. 5867-5870, (1985)). Northern blot analysis and *in situ* hybridization studies suggest that keratin genes K5 and K14 are predominantly transcribed in the proliferating basal layer and transcription of keratin genes K1 and K10 is induced as cells migrate into the spinous layer (Lersch, et al., Mol. and Cell Biol., Vol. 8, pp. 486-493, (1988); Knapp, et al., J. Biol. Chem., Vol. 262, pp. 938-945, (1987); Roop, et al., Cancer Res., Vol. 48, pp. 3245-3252, (1988)). Genes encoding rat (Haydock, et al., J. Biol. Chem., Vol. 261, pp. 12520-12525, (1986)) and mouse (Rothnagel, et al., J. Biol. Chem., Vol. 262, pp. 15643-15648, (1987)) filaggrin have now been identified and *in situ* hybridization experiments have confirmed that transcription of this gene is restricted to the granular layer (Rothnagel, et al., J. Biol. Chem., Vol. 262, pp. 15643-15648, (1987); Fisher, et al. J. Invest. Dermatol., Vol. 88, pp. 661-664, (1987)). To date, loricrin is the only gene encoding a component of the cornified envelope to be studied at the molecular level by *in situ* hybridization and transcripts of this gene are restricted to the granular layer (Mehrel, et al., Cell, Vol. 61, pp. 1103-1112, (1990)).

Since the genes encoding the structured proteins described above are expressed at very high levels, i.e. their individual transcripts represent 5-10% of the total messenger RNA in epidermal cells, their regulatory regions could be utilized in the construction of vectors to direct efficient expression of exogenous DNA in epidermal cells. In particular, efforts have focused on the gene encoding loricrin, a major keratinocyte cell envelope protein (Mehrel et al., Cell, Vol. 61, pp. 1103-1112, (1990)).

-5-

Although this gene is normally only expressed in the most differentiated layers of the epidermis, the present invention demonstrates that it is possible to remove sequences that normally restrict expression of the loricrin gene in undifferentiated cells and achieve high levels of expression in undifferentiated epidermal cells (greater than the viral promoter of SV40). Thus, this vector is constitutively expressed in epidermal cells at all differentiation states.

In addition to the constitutive vector, the present invention takes advantage of the expression characteristics of another gene encoding the K6 keratin to construct an inducible vector. The K6 gene is normally never expressed in the epidermis, but it can be induced under hyperproliferative conditions such as wound healing (Weiss, et al., J. Cell Biol., Vol. 98, pp. 1397-1406, (1984); Nakazawa, et al., J. Cell Biol., Vol. 103, pp. 561a, (1986); Stoler, et al., J. Cell Biol., Vol. 107, pp. 427-446, (1988) and topical application of retinoic acid (Rosenthal et al., J. Invest. Dermatol., Vol. 95, pp. 510-515, (1990)).

SUMMARY OF THE INVENTION

An object of the present invention is a loricrin constitutive vector for efficient expression of nucleic acid sequences in epidermal cells.

An additional object of the present invention is a keratin K6 inducible vector for regulated expression of nucleic acid sequences in epidermal cells.

Another object of the present invention is an *in vivo* method of transducing epidermal cells with a constitutive or inducible vector.

A further object of the present invention is a bioreactor for producing proteins and polypeptides.

An additional object of the present invention is an enhanced method of wound healing or healing of surgical incisions.

Another object of the present invention is a method of treating skin ulcers.

An additional object of the present invention is a method of treating psoriasis.

5 A further object of the present invention is a method of treating cancer.

Thus, in accomplishing the foregoing objects, there is provided in accordance with one aspect of the present invention, a loricrin constitutive vector for efficient expression of nucleic acid sequences in epidermal cells, 10 comprising a 5' flanking region of the loricrin gene, said flanking region including a TATA box, a cap site and a first intron and an intron/exon boundary, all in appropriate sequential and positional relationship for expression of a nucleic acid cassette; a 3' flanking sequence of the loricrin gene; and a linker having a unique restriction endonuclease site at the 15 location of the start and stop codon, said linker connecting the 5' flanking region to the 3' flanking sequence and said linker further providing a position for inserting the nucleic acid cassette which includes the specific nucleic acid sequence to be expressed.

In specific embodiments of the present invention, the loricrin 20 constitutive vector has a 5' flanking region of approximately 1.5 kb, an intron of approximately 1.1 kb and a 3' flanking sequence of approximately 2.1 kb. In specific embodiments of the present invention, the loricrin constitutive vector also includes a poly-linker.

An alternative embodiment of the present invention is a keratin K6 25 inducible vector for regulated expression of a nucleic acid sequence in epidermal cells, comprising a 5' flanking region of the keratin K6 gene, said flanking region including a TATA box, a cap site, a first intron and an intron/exon boundary, all in sequential and positional relationship for expression of a nucleic acid cassette; a 3' flanking sequence of the keratin K6 gene; and a poly-linker having a plurality of restriction endonuclease 30

sites, said poly-linker connecting the 5' flanking region to the 3' flanking sequence and further providing a position for insertion of the nucleic acid cassette which includes the specific nucleic acid sequence to be expressed.

5 In specific embodiments of the present invention, the keratin K6 inducible vector, 5' flanking region of approximately 8.0 kb, an intron and intron/exon boundary of approximately 0.56 kb and the 3' flanking sequence of approximately 1.2 kb.

10 In the present invention, the restriction endonuclease sites in the linker or poly-linker are selected from the group consisting of Cla I, Not I, Xma I, Bgl II, Pac I, Xho I, Nhe I and Sfi I.

In one embodiment of the present invention, the nucleic acid cassette, of the constitutive or inducible vectors, contains a sequence coding for a protein, polypeptide or antisense RNA.

15 In specific embodiments of the present invention, there is a bioreactor comprising transduced epidermal cells including either the loricrin constitutive or keratin K6 inducible vectors. The bioreactor can produce a variety of compounds selected from proteins, polypeptides, antisense RNA.

20 In specific embodiments of the present invention, the loricrin constitutive or keratin K6 inducible vectors are used for the treatment of wounds, surgical incisions, psoriasis, skin ulcers and cancer.

25 The method of the present invention can also be used for vaccination by transducing epidermal cells with a loricrin constitutive or keratin K6 inducible vector having proteins or polypeptides which induce an immunological response.

Another embodiment of the present invention is the nucleotide sequences for the loricrin gene and loricrin constitutive vector.

Another embodiment of the present invention is the nucleotide sequences for the keratin K6 gene and keratin K6 inducible vector.

Other and further objects, features and advantages will be apparent from the following description of the presently preferred embodiments of invention which are given for the purposes of disclosure when taken in conjunction with the accompanying drawings.

5

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic drawing of the mouse loricrin gene and the constitutive epidermal vector derived from its regulatory sequences.

10 **Figure 2** shows the expression characteristics of the constitutive epidermal vector in undifferentiated and differentiated epidermal cells utilizing a reporter gene encoding chloramphenicol acetyl transferase (CAT).

15 **Figure 3** shows the expression characteristics of the constitutive epidermal vector *in vivo* utilizing a reporter gene encoding *E. coli* β -galactosidase.

Figure 4 demonstrates the suppression by Vitamin D₃ of a novel negative regulatory element from the human K1 keratin gene (HK1.NRE).

20 **Figure 5** is a schematic representative of the constitutive epidermal vector which can be suppressed by Vitamin D₃ via insertion of the HK1.NRE.

Figure 6 is a schematic drawing of a derivative of the mouse K6 keratin gene (BCM-MK6(A)-HK1).

25 **Figure 7** shows the expression characteristics of BCM-MK6(A)-HK1 in transgenic animals.

Figure 8 is a schematic drawing of the mouse K6 keratin gene and the proposed construction of an inducible epidermal vector from its regulatory sequences.

Figure 9 is a schematic representative of the inducible epidermal vector which can be suppressed by Vitamin D₃ via insertion of HK1.NRE.

The drawings are not necessarily to scale, and certain features of the invention may be exaggerated in scale and shown in schematic form in the interest of clarity and conciseness.

5

DETAILED DESCRIPTION OF THE INVENTION

It will be readily apparent to one skilled in the art that varying substitutions and modifications may be made to the invention disclosed herein without departing from the scope and spirit of the invention.

10 The term "transformed" as used herein refers to the process or mechanism of inducing changes in the characteristics (expressed phenotype) of a cell by the mechanism of gene transfer whereby DNA is introduced into a cell in a form where it expresses a specific gene product or alters expression of endogenous gene products.

15 The term "transduction" as used herein refers to the process of introducing a DNA expression vector into a cell. Various methods of transduction are possible, including microinjection, CaPO₄, lipofection (lysosome fusion), use of a gene gun and DNA vector transporter.

20 The loricrin constitutive vector and the keratin K6 inducible vector can be transduced into the squamous epithelia cells by any of the variety of ways described above. The types of epithelia cells include epidermis, oral, esophageal, vaginal, tracheal, corneal and other squamous epithelia. They are transduced by contacting the vector with the cells. In the preferred embodiment this includes using a gene gun or DNA vector transporter.

25 The term "DNA vector transporter" as used herein refers to those molecules which bind to DNA vectors and are capable of being taken up by epidermal cells. DNA transporter is a molecular complex capable of non-covalent binding to DNA and efficiently transporting the DNA through the cell membrane. Although not necessary, it is preferable that the transporter also transport the DNA through the nuclear membrane.

-10-

The term "nucleic acid cassette" as used herein refers to the genetic material of interest which can express a protein polypeptide or RNA and which is capable of being incorporated into the epidermal cells. The nucleic acid cassette is positionally and sequentially oriented within the 5 keratin K6 inducible vector or the loricrin constitutive vector such that the nucleic acid in the cassette can be transcribed into RNA or antisense RNA and, when necessary, translated into proteins or polypeptides in the transformed epidermal cells. A variety of proteins and polypeptides can be expressed by the sequence in the nucleic acid cassette in the 10 transformed epidermal cells. These proteins or polypeptides which can be expressed include hormones, growth factors, enzymes, clotting factors, apolipoproteins, receptors, drugs, tumor antigens, viral antigens, parasitic antigens and bacterial antigens. Specific examples of these compounds include proinsulin, insulin, growth hormone, insulin-like growth factor I, 15 insulin-like growth factor II, insulin growth factor binding protein, epidermal growth factor TGF- α , dermal growth factor PDGF, angiogenesis factors, e.g., acid fibroblast growth factor, basic fibroblast growth factor and angiogenin for instance, matrix proteins such as Type IV collagen, Type VII collagen, laminin and proteins from viral, bacterial and parasitic 20 organisms which can be used to induce immunologic response.

The genetic material which is incorporated into the epidermal cells using the loricrin constitutive vector or the keratin K6 inducible vector includes DNA not normally found in epidermal cells, DNA which is normally found in epidermal cells but not expressed at physiological 25 significant levels, DNA normally found in epidermal cells and normally expressed at physiological desired levels, any other DNA which can be modified for expression in epidermal cells, and any combination of the above.

The term "loricrin constitutive vector" as used herein refers to a 30 vector which can be inserted into epidermal cells and which once inserted,

-11-

will express a constitutive (*i.e.*, a constant level) of protein, polypeptide or antisense RNA from the nucleic acid cassette which is part of the loricrin constitutive vector. The loricrin constitutive vector is used for efficient expression of a nucleic acid sequence in epidermal cells and is comprised of a 5' flanking region of the loricrin gene, said flanking region including a TATA box, a cap site and a first intron and an intron/exon boundary all in appropriate sequential and positional relationship for expression of a nucleic acid cassette; a 3' flanking sequence of the loricrin gene; and a linker having a unique restriction endonuclease site at the location of the 5
start and stop codon, said linker connecting the 5' flanking region to the 10 3' flanking sequence and said linker further providing a position for inserting the nucleic acid cassette.

The sequence for the loricrin gene which is used for preparing the loricrin constitutive vector is shown in SEQ. ID No. 1. The loricrin 15 constitutive vector has a 5' flanking region comprising nucleotides 1 to 1540 of SEQ. ID. No. 1; an intron and intron/exon boundary comprising nucleotides 1587 to 2677 of SEQ. ID. No. 1, a 3' flanking region comprising nucleotides 4384 to 6530 of SEQ. ID. No. 1; and a linker to be inserted at the unique Cla I site at nucleotides 2700 to 2705 of SEQ. ID. 20 No. 2. The loricrin constitutive vector has a 5' flanking region of approximately 1.5 kb, an intron of approximately 1.1 kb and a 3' flanking sequence of approximately 2.1 kb. The linker of the loricrin constitutive vector can be a poly-linker. The poly-linker includes a plurality of restriction endonuclease sites.

25 The term "keratin K6 inducible vector" as used herein is a vector which is useful for regulated expression of a nucleic acid sequence in epidermal cells. The keratin K6 inducible vector comprises a 5' flanking region of the keratin K6 gene, said flanking region including a TATA box, a cap site, a first intron and an intron/exon boundary all in sequential and 30 positional relationship for the expression of a nucleic acid cassette; a 3'

-12-

flanking sequence of a keratin K6 gene; and a poly-linker. The poly-linker includes a plurality of restriction endonuclease sites, connects the 5' flanking region to the 3' flanking sequence and further provides a position for insertion of the nucleic acid cassette.

5 The partial sequence for the keratin K6 gene which is used for preparing the keratin K6 inducible vector is shown in schematic form in Figure 8 and the sequence is shown in SEQ. ID No. 3. The keratin inducible vector has a 5' flanking region which extends from a unique 5' Xho I site up to nucleotide 360 of SEQ. ID. No. 3; an intron and
10 intron/exon boundary comprising nucleotides 928 to 1494 of SEQ. ID. No. 3; a 3' flanking region which extends from nucleotide 4740 of SEQ. ID. No. 3 to a unique 3' Xho I site; and a poly linker inserted between nucleotides 1504 to 1509 of SEQ. ID. No. 3.

15 The keratin K6 inducible vector has a 5' flanking region of approximately 8.0 kb, an intron and intron/exon boundary of approximately 0.56 kb and a 3' flanking sequence of approximately 1.2 kb. The restriction endonuclease sites found in the linker and poly-linker of the loricrin and keratin K6 vectors can be any restriction endonucleases which will allow insertion of the nucleic acid cassette. In the preferred
20 embodiment they are usually selected from the group consisting of Cla I, Not I, Xma I, Bgl II, Pac I, Xho I Nhe I and Sfi I.

25 One skilled in the art will readily recognize that there are a variety of ways to introduce the loricrin constitutive vector or the keratin K6 inducible vector into epidermal cells. The vectors can be inserted either *in vivo* or *ex vivo*. The mode of insertion will, to a certain degree, determine the available methods for the insertion.

30 One embodiment of the present invention includes a bioreactor. A bioreactor is comprised of transformed epidermal cells which contain the loricrin constitutive vector or contain the keratin K6 inducible vector. Once the vector is inserted in the epidermal cells, the epidermal cells will

-13-

express the nucleic cassette and produce the protein, polypeptide or antisense RNA of interest. This can be done either *in vivo* or *ex vivo*. Any compound which can be encoded in, and expressed by, the nucleic acid cassette can be produced by the bioreactor.

5 One method for *ex vivo* introduction of the loricrin constitutive vector or the keratin K6 inducible vector into epidermal cells includes a cotransfection of the vector with a selectable marker. The selectable marker is used to select those cells which have become transformed. The cells can then be used in any of the methods described in the present
10 invention.

15 One specific embodiment of the present invention is a method for the enhanced healing of a wound or surgical incision. This method comprises the *in vivo* transduction of epidermal cells with a loricrin constitutive vector or a keratin K6 inducible vector. In either case, the nucleic acid cassette of said vector contains a nucleic acid sequence for a
20 growth factor.

25 In the preferred embodiment for the treatment of wounds or surgical incisions, a plurality of vectors are introduced into the epidermal cells. In the plurality of vectors, the cassette of at least one vector contains a nucleic acid sequence for an epidermal growth factor (TGF- α), the cassette of at least one vector contains a dermal growth factor (PDGF), a cassette of at least one vector contains a nucleic acid sequence for a matrix protein to anchor the epidermis to the dermis, and a cassette of at least one vector contains a nucleic acid sequence for an angiogenesis factor. The sequence for matrix proteins can be selected from any sequences useful for the anchoring of the epidermis to the dermis but are usually selected from the group consisting of Type IV collagen, laminin, nidogen, and Type VII collagen. The angiogenesis factor is usually selected from the group consisting of acid fibroblast growth factor, basic
30 fibroblast growth factor and angiogenin. The combination of the vectors

provides all of the necessary elements for quick and rapid enhancement of healing of wounds or surgical incisions. This procedure is very helpful in the case of plastic or reconstructive surgery. Furthermore, skin ulcers 5 can be treated by following similar procedures as described for wound healing or surgical incision. These procedures are useful in animals and humans.

In the *ex vivo* approach for treating or healing wounds, surgical 10 incisions and skin lesions, the vectors are first transduced into the epidermal cells *ex vivo*. The transformed epidermal cells are transplanted onto the animal or human to be treated.

Another embodiment of the present invention is a method for 15 treating psoriasis. In this method, epidermal cells are transduced *in vivo* with a loricrin constitutive vector or a keratin K6 inducible vector. A nucleic acid cassette in said vector contains a nucleic acid sequence for a protein or polypeptide selected from the group consisting of TGF- β , a soluble form of cytokine receptor, and an antisense RNA. The cytokine receptor can be selected from the group consisting of IL-1, IL-6 and IL-8. The antisense RNA sequence is selected from the group consisting of 20 TGF- α , IL-1, IL-6 and IL-8.

In another embodiment of the present invention there is a method 25 of treating cancer. This method comprises the steps of *in vivo* transduction of epidermal cells with a loricrin constitutive vector or a keratin K6 inducible vector into epidermal cells. The nucleic acid cassette of either vector contains the nucleic acid sequence coding for antisense RNA for the E6 or E7 gene of the human papilloma virus or coding for the normal p53 protein. Although the example given is for skin cancer, this same approach is used for cancers occurring in other squamous epithelial, since the constitutive and inducible vectors will also function in these tissue types.

-15-

It has been found that either the keratin K6 inducible vector or the loricrin constitutive vector can be further regulated by introducing the Vitamin D regulatory element into the vector. The Vitamin D regulatory element is usually introduced into the 3' flanking sequence. In the 5 present invention, the Vitamin D regulatory element is from the human K1 keratin gene. With the Vitamin D regulatory element in the vector, the expression of the nucleic acid cassettes can be suppressed by Vitamin D, a commonly used substance in animals and humans.

10 An additional embodiment of the present invention is a method for vaccination comprising the step of *in vivo* introduction of a loricrin constitutive vector into epidermal cells. The nucleic acid cassette in the vectors usually codes for a polypeptide which induces an immunological response. An example of this is the viral capsid protein from the human papilloma virus. One skilled in the art will readily recognize that any 15 other variety of proteins can be used to generate a immunologic response and thus produce antibodies for vaccination.

The following examples are offered by way of illustration and are not intended to limit the invention in any manner.

20

EXAMPLE 1

Isolation of the Mouse Loricrin Gene

25 Although it is a major keratinocyte cell envelope protein, loricrin was not identified until 1990 (Mehrel, et al., Cell, Vol. 61, pp. 1103-1112, (1990)). The primary sequence of the loricrin protein was deduced from the overlapping cDNA clones described in Mehrel, *id.* To obtain the full gene, the cDNA clones were used to screen an EMBL-3 Balb/c mouse genomic library. The gene encoding loricrin was located within two Bam HI fragments of 3.4 and 3.1 kb. The coding sequence within this genomic fragment is identical to the cDNA sequences and is not interrupted by 30 introns. There is, however, an intron in the 5' non-coding region that is

-16-

approximately 1.1 kb in length. In addition to the intron and coding sequence, there is approximately 1.5 kb of 5' flanking sequence and 2.1 kb of 3' flanking sequence.

5

EXAMPLE 2

Construction and characterization of a constitutive epidermal expression vector from the mouse loricrin gene

10 Although all of the regulatory elements of the loricrin gene have not been identified, a functional loricrin constitutive expression construct was designed as follows. Briefly, polymerase chain reaction (PCR) technology was used to delete the loricrin coding region, leaving the 5' and 3' flanking regions, 5' and 3' non-coding regions and the intron (Figure 1). A unique Cla I restriction site was engineered at the start (ATG) and stop (TAA) codons to allow easy insertion of exogenous gene 15 cassettes. To assess the expression characteristics of this vector, a reporter gene, the bacterial gene encoding chloramphenicol acetyl transferase (CAT), was inserted into the Cla I site. The expression vector was analyzed by transient transfection into primary mouse epidermal cells. Positive (pSV2.CAT, lane 1) and negative (pA10.CAT, lane 2) control vectors were included in the assay (Figure 2). The loricrin expression 20 vector had high activity in undifferentiated (low Ca²⁺ medium, lane 3) and differentiated (high Ca²⁺ medium, lane 4) epidermal cells, surpassing levels obtained with the strong promoter of the virus SV40. This result was unexpected, since previous *in vivo* studies had demonstrated that the loricrin gene was only expressed at a late stage of epidermal differentiation (Mehrel, et al., Cell, Vol. 61, pp. 1103-1112, (1990)), and indicates that additional flanking sequences are required to suppress 25 loricrin expression in undifferentiated epidermal cells.

30 To analyze the expression characteristics of the loricrin vector *in vivo*, the bacterial gene encoding β -galactosidase was inserted into the Cla

I site. The β -galactosidase gene has frequently been used as a reporter gene to assess targeting specificity (MacGregor, et al., In: Methods in Molecular Biology, Vol. 7, pp. 217-235, (1991)). This construct was designated pML- β -gal and was used in the production of transgenic mice.

5 This construct was digested with Apa I and subjected to preparative agarose gel electrophoresis to purify the pML- β -gal expression construct away from plasmid sequences (pGEM72) which might interfere with expression. The separated expression construct sequences were purified and recovered using NA 45 DEAE membrane (Schleicher & Schuell).

10 DNA was precipitated and resuspended at 1-3 ng/ μ l. ICR outbred female mice (Sasco) were given PMS and HCG to stimulate superovulation, mated to FVB males (Taconic) and resulting one-cell fertilized embryos were collected from the oviducts. DNA was micro-injected into the pronuclei and the embryos were surgically transferred to pseudopregnant recipient females (the result of mating ICR females with vasectomized B₆D₂F₁ males (Taconic). Normal gestation and birth was allowed to continue and at approximately three weeks of age the pups were screened for evidence of the transgene using total genomic DNA extracted from the tail.

15

20 PCR analysis was performed on the extracted tail using oligo primers specific for β -galactosidase. Animals positive for the transgene were further analyzed to assess the expression characteristics of pML- β -gal. This was done by removing part of the ear and incubating the tissue in a staining solution containing X-gal. This was done by removing part of the ear and incubating the tissue in a staining solution containing X-gal. Typical results are seen in Figure 3 where a PCR positive animal expressed high levels of β -galactosidase in the epidermis (Figure 3b) while a PCR negative animal shows no such staining (Figure 3a) indicating that endogenous murine β -galactosidase is not expressed at sufficient levels in the epidermis to cause false positives in this assay. Intense X-gal staining

25

-18-

was detected in the basal compartment as well as the suprabasal, more differentiated layers.

5 To analyze the expression characteristics of the loricrin vector *in vivo*, the bacterial gene encoding β -galactosidase was inserted into the Cla I site. This data is shown in Figure 3. This observation indicates that the loricrin expression vector is useful as a constitutive vector to direct the efficient expression of exogenous DNA in both the undifferentiated and differentiated compartments of the epidermis.

10

EXAMPLE 3

Utilization of a novel Vitamin D₃ responsive element to modulate expression levels in the epidermis

15 This example demonstrates that a novel negative regulatory element from the human K1 keratin gene (HK1.NRE) is able to suppress a heterologous promoter in response to Vitamin D₃. The HK1.NRE is 70 nucleotides in length (see Figure 4). PCR technology was used to generate Bam HI and Bgl II sites at opposite ends of this fragment. This facilitates generating multiple copies of this fragment since ligation and digestion 20 with Bam HI and Bgl II will select for oligomers which have ligated head to tail. Four tandem copies of the HK1.NRE were inserted into the Bgl II cloning site of pA10.CAT. In the absence of Vitamin D₃, this construct is highly expressed when transfected into primary mouse epidermal cells (Figure 4). The addition of increasing concentrations of Vitamin D₃ to the culture medium completely suppresses transcription of this heterologous 25 promoter. Thus, by using Vitamin D₃, the activity of the expression vector is modulated. Figure 5 shows a schematic representative of a derivative of the loricrin constitutive epidermal vector which contains the HK1.NRE in its 3' flanking region. The activity of this vector within epidermal cells

-19-

can be suppressed by topical application of Vitamin D₃, or an analogue, to the skin.

EXAMPLE 4

5 Isolation and characterization of a Mouse K6 Keratin Gene
Several laboratories have reported that keratin K6 is not expressed in normal epidermis, but is expressed under hyperproliferative conditions such as wounding (Weiss, et al., J. Cell Biol., Vol. 98, pp. 1397-1406, 1984); Nakazawa, et al., J. Cell Biol., Vol. 103, pp. 561a (1986); Stoler, et
10 al., J. Cell Biol., Vol. 107, pp. 427-446, (1988)) or topical application of retinoic acid (Rosenthal, et al., J. Invest. Dermatol., Vol. 95, pp. 510-515, 1990). Although K6 expression does not occur in interfollicular epidermis, it does occur in hair follicles (Nakazawa, et al., J. Cell Biol., Vol. 103, pp. 561a, (1986)). Recent results indicate that there are two K6
15 cDNAs that differ in sequence in only a few nucleotides. These cDNA clones have been used to differentially screen a EMBL 3 Balb/c mouse genomic library and isolate two distinct K6 genes. These genes are closely linked within genomic DNA, i.e., arranged in tandem. They have almost identical 3' halves, including identical 3' non-coding and flanking regions.
20 Interestingly, the 5' halves of the 2 genes differ greatly in their restriction fragment patterns. Sequence analysis of the region near the ATG shows many differences between the two genes. The sequence of one of these genes, designated BCM-MK6(A), is shown in SEQ. ID. No. 3. To determine the expression characteristics of this gene *in vivo* in transgenic
25 mice, PCR technology was used to modify a 13.5 kb Xho I fragment containing BCM-MK6(A). Nucleotides encoding the C-terminal region of the K6 protein were deleted and nucleotides encoding the amino acid sequence SEQ. ID. No. 4 were inserted. These amino acids are at the C-terminal of human keratin K1 (Johnson, et al., PNAS, USA, Vol. 82, pp.
30 1896-1900, (1985)). A schematic representative of this derivative of the

-20-

mouse K6 gene (BCM-MK6(A)-HK1) is shown in Figure 6. Antisera have previously been generated against the HK1 C-terminal peptide (Rosenthal, et al., J. Invest. Dermatol., Vol. 95, pp. 510-515, (1990)). These antibodies are monospecific for this human K1 peptide and allow expression of the derivatized BCM-MK6(A)-HK1 transgene to be followed against the expression pattern of the endogenous mouse K6 genes.

The derivatized mouse K6 transgene shown in Figure 6 was used in the production of transgenic mice as outlined in Example 2. Mice resulting from the initial injections were screened by PCR analysis for presence of the BCM-MK6(A)-HK1 transgene. Positive founders were initially analyzed for transgene expression as follows. A small ear biopsy was taken and after 48 hours a second biopsy was taken at the same site to score for expression during wound healing. Transgene expression was limited to hair follicles in the initial biopsy and was not present in interfollicular epidermis. Transgene expression was observed in the epidermis in the 48 hour biopsies, but only at the site of wounding. To further confirm the inducibility of the BCM-MK6(A)-HK1 transgene under hyperproliferative conditions, F1 generation offspring from the initial founders were treated topically with the hyperplasiogenic agent 12-O-tetradecanoylphorbol-13-acetate. Biopsies were taken before and 48 hours after topical application of this agent. Immunofluorescence was performed on frozen sections of these biopsies with antisera specific for the HK1 peptide. No expression was observed prior to the induction of hyperplasia, however, the BCM-MK6(A)-HK1 protein was expressed at very high levels in all layers of the epidermis 48 hours after hyperplasia was induced (Figure 7).

-21-

EXAMPLE 5

Construction of an inducible epidermal expression vector from the mouse K6 gene (BCM-MK6(A))

Results obtained with the derivative of BCM-MK6(A) (Figure 7) indicate that all of the regulatory sequences required to suppress expression of this gene in normal epidermis and activate its expression under hyperproliferative conditions, such as in wounding healing or experimentally induced hyperplasia, are located within the 13.5 kb Xho I fragment (Figure 6). Therefore, an inducible vector was developed from this fragment. This vector is very useful in gene therapy applications where dosage of pharmaceuticals needs to be regulated. In addition, this vector is ideally suited for wound healing applications since it is induced during the wound healing process but suppressed after healing has occurred. Figure 8 illustrates how a vector is constructed from the BCM-MK6(A) gene. The vector is derived from the 13.5 kb Xho I fragment which contains the entire K6 gene. The same general strategy used in construction of the constitutive epidermal vector (Figure 1) is followed. The expression vector retains all of the 5' flanking sequences, the 5' non-coding sequences up to but not including the ATG, the first intron including the splice-sites of the intron-exon boundary and all of the 3' non-coding and flanking sequences after the TAA codon. A polylinker is engineered 3' of the first intron to allow easy insertion of exogenous DNA cassettes. These manipulations are performed through the use of PCR technology. Unique Xho I sites are conserved at the ends of the vector to allow easy amplification in pGEM vectors and excision for purification from plasmid sequences. Recent *in vivo* results indicate that the endogenous human K6 gene is inducible after topical application of all-trans retinoic acid. Further, *in vivo* mouse experiments suggest that the vector shown in Figure 9 is inducible by topical application of retinoic acid, or an analogue, to the skin.

-22-

EXAMPLE 6

Construction of a derivative of the inducible epidermal vector which could be suppressed by Vitamin D₃

Even though the inducible epidermal vector depicted in Figure 8 is suppressed or silent in normal epidermis, it can be accidentally induced as a result of injury. Therefore, it is desirable to have an additional suppressor engineered into this construct. In addition, this suppressor is used to more tightly regulate pharmaceutical delivery. This is achieved by insertion of the HK1.NRE described in Figure 4. Figure 9 shows a schematic representative of a derivative of the K6 inducible epidermal vector which contains the HK1.NRE in its 3' flanking region. The activity of this vector within epidermal cells is suppressed by topical application of Vitamin D₃, or an analogue, to the skin.

15

EXAMPLE 7

Utilization of the inducible epidermal vector in wound healing

Greater than 3.5 million individuals develop skin ulcers. During normal healing, epidermal cells produce growth factors which affect not only epidermal cells but also cells within the dermis. In addition, epidermal cells synthesize several matrix proteins which provide an anchor to the underlying dermis. Many skin ulcers occur in patients with disorders such as circulatory problems and diabetes, and the normal healing process is impaired. The inducible epidermal vector is used to target the combined expression of growth factors, to accelerate growth of cells in both the epidermal and dermal compartments; matrix proteins, to increase tensile strength; and angiogenesis factors, to improve circulation, in an attempt to improve healing these patients.

-23-

EXAMPLE 8

Utilization of the constitutive epidermal vector in gene therapy approaches to cancer

Skin cancer is by far the most common form of cancer with greater
5 than 600,000 new cases reported each year. Several genes have been
implicated in causing skin cancer, including loss or mutation of the host
cell tumor suppressor gene, p 53 and expression of the E6 and E7
transforming genes of human papilloma virus (HPV). *In vitro* studies
suggest that the normal or wild type p53 gene can revert the phenotype
10 of malignant cells or induce programmed cell death. The constitutive
epidermal vector is used to target expression of the normal p53 gene to
cause reversion to a non-malignant phenotype or induction of programmed
death *in vivo*. In cancers where HPV is suspected of being the etiological
agent, the constitutive vector is used to target expression of antisense
15 RNA specific for the E6 and E7 genes of HPV.

EXAMPLE 9

Utilization of the epidermal vector systems in gene therapy approaches to psoriasis

Psoriasis is a common inherited skin disease which affects
20 approximately 4 million individuals in the U.S., 20 million world-wide. It
is characterized by the presence of inflamed scaly skin. Although the
specific defect for psoriasis is not known, inappropriate expression of
growth factors, and cytokines appears to be responsible for its
25 pathogenesis. Epidermal vectors are used to inhibit the mitogenic effects
of positive growth factors produced in psoriatic lesions by expressing
negative growth factors which induce growth arrest of epidermal cells.

The inflammation observed in psoriasis most likely results from
inappropriate expression of cytokines. Targeted expression of soluble
30 cytokine receptors prevents stimulation of an inflammatory infiltrate in

-24-

this disease. In another approach, antisense RNA is directed against transcripts of positive growth factors or cytokines. These approaches have therapeutic potential for other dermatoses resulting from inflammation.

5 All patents and publications mentioned in this specification are indicative of the levels of those skilled in the art to which the invention pertains. All patents and publications which are incorporated herein by reference are incorporated to the same extent as if each individual publication was specifically and individually indicated to be incorporated by reference.

10 One skilled in the art will readily appreciate that the present invention is well adapted to carry out the objects and obtain the ends and advantages mentioned, as well as those inherent therein. The bioreactors, nucleic acid sequences, transformed epidermal cells, loricrin constitutive vector and keratin K6 inducible vector, along with the methods, 15 procedures, treatments, molecules of specific compounds described herein are presently representative of preferred embodiments, are exemplary and are not intended as limitations on the scope of the invention. Changes therein and other uses will occur to those skilled in the art which are encompassed within the spirit of the invention as defined by the scope of 20 the claims.

CLAIMS

What we claim is:

1. A loricrin constitutive vector for efficient expression of a nucleic acid sequence in epidermal cells, comprising:
 - 5 a 5' flanking region of the loricrin gene, said flanking region including a TATA box, a cap site and a first intron and intron/exon boundary all in appropriate sequential and positional relationship for expression of a nucleic acid cassette;
 - 10 a 3' flanking sequence of the loricrin gene; and
 - 15 a linker having a unique restriction endonuclease site at the location of the start and stop codon, said linker connecting the 5' flanking region to the 3' flanking sequence and said linker further providing a position for inserting the nucleic acid cassette.
2. The loricrin constitutive vector of claim 1, wherein the 5' flanking region is approximately 1.5 kb, the intron is approximately 1.1 kb and the 3' flanking sequence is approximately 2.1 kb.
3. The loricrin constitutive vector of claim 1, wherein the unique restriction site is selected from the group consisting of Cla I, Not I, Xma I and Bgl II, Pac I, Xho I, Nhe I and Sfi I.
- 20 4. The loricrin constitutive vector of claim 1, wherein the linker is a poly-linker, said poly-linker including a plurality of restriction endonuclease sites.
5. A keratin K6 inducible vector for regulated expression of a nucleic acid sequence in epidermal cells, comprising:
 - 25 a 5' flanking region of the keratin K6 gene, said flanking region including a TATA box, a cap site, a first intron and intron/exon boundary sequence all in sequential and positional relationship for expression of a nucleic acid cassette;
 - 30 a 3' flanking sequence of the keratin K6 gene; and

a poly-linker having a plurality of restriction endonuclease sites, said poly-linker connecting the 5' flanking region to the 3' flanking sequence and further providing a position for insertion of the nucleic acid cassette.

- 5 6. The keratin K6 inducible vector of claim 5, wherein the 5' flanking region is approximately 8.0 kb and the intron and intron/exon boundary is approximately 0.56 kb and the 3' flanking sequence is approximately 1.2 kb.
7. The vector according to claims 1, 4 or 5, wherein the cassette includes a nucleic acid sequence coding for a protein or polypeptide selected from the group consisting of a hormone, a growth factor, an enzyme, a clotting factor, an apolipoprotein, a receptor, a drug and a tumor antigen.
- 10 8. The vector according to claims 4 or 5, wherein the plurality of restriction endonuclease sites are selected from the group consisting of Cla I, Not I, Xma I, Bgl II, Pac I, Xba I, Nhe I and Sfi I.
- 15 9. A method for *in vivo* transduction of epidermal cells with a loricrin constitutive vector comprising the step of contacting the vector with epidermal cells for sufficient time to transfet the epidermal cells.
- 20 10. A method for *in vivo* transduction of epidermal cells with a keratin K6 inducible vector comprising the step of contacting the vector with epidermal cells for sufficient time to transfet the epidermal cells.
11. A bioreactor comprising transformed epidermal cells including the loricrin constitutive vector of claim 1.
- 25 12. A bioreactor comprising transformed epidermal cells including the keratin K6 inducible vector of claim 5.
13. The bioreactor according to claims 11 or 12 wherein the loricrin constitutive vector includes a cassette having a nucleic acid sequence coding for a protein or polypeptide selected from the group consisting of a hormone, a growth factor, an enzyme, a drug, a tumor suppressor,
- 30

a receptor, an apolipoprotein, a clotting factor a tumor antigen, a viral antigen, a bacterial antigen and a parasitic antigen.

14. The bioreactor of claim 13, wherein the nucleic acid sequence encodes proinsulin or insulin.

5 15. The bioreactor of claim 13, wherein the nucleic acid sequence encodes growth hormone.

16. The bioreactor of claim 13, wherein the nucleic acid sequence encodes insulin-like growth factor I, insulin-like growth factor II or insulin growth factor binding protein.

10 17. The bioreactor of claim 13, wherein the nucleic acid sequence encodes antihemophilic factor (Factor VIII), Christmas factor (Factor IX) or Factor VII.

18. The bioreactor of claim 13, wherein the nucleic acid sequence encodes an epidermal growth factor (TGF- α), a dermal growth factor (PDGF)

15 19. The bioreactor of claim 13, wherein the nucleic acid sequence encodes Type IV collagen, laminin, nidogen, or Type VII collagen.

20. The bioreactor of claim 13 for vaccine production, wherein the cassette includes a protein which induces an immunological response.

21. A method for *ex vivo* introduction of a loricrin constitutive vector into epidermal cells comprising the steps of co-transfected the vector with a selectable marker and selecting the transformed cells.

22. A method for *ex vivo* introduction of a keratin K6 inducible vector into epidermal cells comprising the steps of co-transfected the vector with a selectable marker and selecting the transformed cells.

25 23. A loricrin gene of SEQ. ID. No. 1.

24. A loricrin constitutive vector having:
a 5' flanking region comprising nucleotides 1 to 1540 of SEQ.
ID. No. 1;

-46-

an intron and intron/exon boundary comprising nucleotides 1587 to 1679 of SEQ. ID. No. 1;

a 3' flanking region comprising nucleotides 4384 to 6530 of SEQ. ID. No. 1; and

5 a linker to be inserted at the unique *Cla* I site at nucleotides 2700 to 2705 SEQ. ID. No. 2

25. 26. A keratin K6 gene of SEQ. ID. No. 3.

10 26. A keratin K6 inducible vector having:

a 5' flanking region which extends from a unique 5' *Xho* I site up to nucleotide 360 of SEQ. ID. No. 3;

15 an intron and intron/exon boundary comprising nucleotides 928 to 1494 of SEQ. ID. No. 3.

a 3' flanking region which extends from nucleotide 4740 of SEQ. ID. No. 3 to a unique 3' *Xho* I site; and

15 a poly-linker inserted between nucleotides 1504 to 1509 of SEQ. ID. No. 3

27. 28. A method for enhanced healing of a wound or surgical incision comprising the steps of *in vivo* transduction of epidermal cells with a loricrin constitutive vector, wherein said vector includes a nucleic acid cassette having nucleic acid sequence for a growth factor.

20 28. A method of enhanced healing of a wound or surgical incision comprising the step of *in vivo* transduction of epidermal cells with a keratin K6 inducible vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence for a growth factor.

25 29. The method according to claims 27 or 28, wherein the epidermal cells are transduced with a plurality of vectors and wherein the cassette of at least one vector includes the nucleic acid sequence of epidermal growth factor (TGF- α), the cassette of at least one vector includes dermal growth factor (PDGF), the cassette of at least one vector includes the nucleic acid sequence for a matrix protein to anchor the

30

epidermis to the dermis and the cassette of at least one vector includes the nucleic acid sequence for an angiogenesis factor.

30. The method of claim 29, wherein the sequence for the matrix protein is selected from sequences coding for a protein selected from the group consisting of Type IV collagen, laminin, nidogen and Type VII collagen.

5 31. The method of claim 29, wherein the angiogenesis factor is selected from the group consisting of acid fibroblast growth factor, basic fibroblast growth factor and angiogenin.

32. A method of treating skin ulcers comprising the steps of *in vivo* transduction of epidermal cells with a loricrin constitutive vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence for a growth factor.

10 33. A method of treating skin ulcers comprising the steps of *in vivo* transduction of epidermal cells with a keratin K6 inducible vector, wherein said vectors include a nucleic acid cassette having a nucleic acid sequence for a growth factor.

15 34. The method according to claims 32 or 33, wherein the epidermal cells are transduced with a plurality of vectors and wherein the cassette of at least one vector includes the nucleic acid sequence of epidermal growth factor (TGF- α), the cassette of at least one vector includes dermal growth factor (PDGF), the cassette of at least one vector includes the nucleic acid sequence for a matrix protein to anchor the epidermis to the dermis and the cassette of at least one vector includes the nucleic acid sequence for an angiogenesis factor.

20 25 35. The method of claim 34, wherein the sequence for the matrix protein is selected from sequences coding for a protein selected from the group consisting of Type IV collagen, laminin, nidogen, and Type VII collagen.

36. The method of claim 34, wherein the angiogenesis factor is selected from the group consisting of acid fibroblast growth factor, basic fibroblast growth factor and angiogenin.
37. A method of enhanced healing of a wound, surgical incision or skin ulcers in humans and animals comprising the steps of:
 - ex vivo* transduction of epidermal cells with a loricrin constitutive vector, wherein said vector includes a nucleic acid cassette a nucleic acid sequence for a growth factor; and
 - transplanting said transduced epidermal cells into the animal or human to be treated.
38. A method of enhanced healing of a wound, surgical incision or skin ulcers in humans and animals, comprising the steps of:
 - ex vivo* transduction of epidermal cells with a keratin K6 inducible vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence for a growth factor; and
 - transplanting said transduced epidermal cells into the animal or human to be treated.
39. The method according to claims 37 or 38, wherein the epidermal cells are transduced with a plurality of vectors and wherein the cassette of at least one vector includes the nucleic acid sequence of epidermal growth factor (TGF- α), the cassette of at least one vector includes dermal growth factor (PDGF), the cassette of at least one vector includes the nucleic acid sequence for a matrix protein to anchor the epidermis to the dermis and the cassette of at least one vector includes the nucleic acid sequence for an angiogenesis factor.
40. The method of claim 39, wherein the sequence for the matrix protein is selected from sequences coding for a protein selected from the group consisting of Type IV collagen, laminin, nidogen and Type VII collagen.

41. The method of claim 39, wherein the angiogenesis factor is selected from the group consisting of acid fibroblast growth factor, basic fibroblast growth factor and angiogenin.
42. A method for treating psoriasis comprising the step of *in vivo* transduction of epidermal cells with a loricrin constitutive vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence coding for a protein or polypeptide selected from the group consisting of TGF- β , a soluble form of cytokine receptor, and an antisense RNA.
- 10 43. A method for treating psoriasis comprising the step of *in vivo* transduction of epidermal cells with a keratin K6 inducible vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence coding for a protein or polypeptide selected from the group consisting of TGF- β , a soluble form of cytokine receptor, and an antisense RNA.
- 15 44. The method of claims 42 or 43 wherein the cassette contains the sequence for TGF- β .
45. The method of claims 42 or 43 wherein the cassette contains a soluble form of cytokine receptor selected from the group consisting of IL-1, IL-6 and IL-8.
- 20 46. The method of claims 42 or 43 wherein the cassette contains antisense RNA to TGF- α , IL-1, IL-6 or IL-8.
47. A method of treating cancer of squamous epithelia comprising the step of *in vivo* transduction of squamous epithelia cells with a loricrin constitutive vector or a keratin K6 vector, said vector includes a nucleic acid cassette having a nucleic acid sequence coding for an antisense RNA.
- 25 48. The method of claim 47 wherein the squamous epithelia cells are selected from the group of cells consisting of epidermis, oral, esophageal, vaginal, tracheal and corneal epithelia.
- 30

49. The method of claim 47 for treating skin cancer wherein transduction of epidermal cells is with a loricrin constitutive vector and said nucleic acid cassette has a nucleic acid sequence coding for an antisense RNA for the E6 or E7 gene of human papilloma virus.
- 5 50. The method of claim 47 for treating skin cancer wherein transduction of epidermal cells is with a loricrin constitutive vector and said nucleic acid cassette has a nucleic acid sequence coding for the normal p53 protein.
51. The method of claim 47 for treating skin cancer wherein transduction of epidermal cells is with a keratin K6 vector and said nucleic acid cassette has a nucleic acid sequence coding for an antisense RNA for the E6 or E7 gene of human papilloma virus.
- 10 52. The method of claim 47 for treating skin cancer wherein transduction of epidermal cells is with a keratin K6 vector and said nucleic acid cassette has a nucleic acid sequence coding for the normal p53 protein.
53. The vector according to claims 1, 4 or 5, further including a Vitamin D regulatory element.
54. The vector of claim 53, wherein the Vitamin D regulatory element is from the human K1 keratin gene.
- 20 55. A method for vaccination comprising the step of the *in vivo* transduction of epidermal cells with a loricrin constitutive vector or a keratin K6 inducible vector, wherein said vector includes a nucleic acid cassette having a nucleic acid sequence coding for a protein or polypeptide which induces an immunological response.
- 25 56. The method of claim 55, wherein the cassette includes a sequence for a viral capsid protein.
57. The method of claim 56, wherein the capsid protein is from the human papilloma virus.
58. A transgenic animal containing the vector of claims 1, 4 or 5 in its germ and somatic cells, wherein said vector was introduced into said

-51-

animal or an ancestor of said animal at an embryonic stage and the nucleic acid cassette of said vector is only expressed in squamous epithelia.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US93/03993

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) :Please See Extra Sheet.

US CL :435/320.1, 284, 285, 286; 424/93B; 536/23.5; 800/2

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : Please See Extra Sheet.

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, MEDLINE, CAS, BIOSIS, WORLD PATENTS INDEX
search terms: loricrin, keratin K6, epidermal vector

C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category* | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
|-----------|--|-----------------------|
| Y | US, A, 5,087,617 (Smith) 11 February 1992, see col. 3, lines 31-38. | 42-52 |
| Y | US, A, 5,057,411 (Lancaster et al) 15 October 1991, see col. 3, lines 56-64. | 55-57 |
| Y | US, A, 5,008,240 (Bentz et al) 16 April 1991, see col. 16, lines 44-61. | 42-46 |

Further documents are listed in the continuation of Box C.

See patent family annex.

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

- I. Claims 1-4, 11, 21, 23 and 24, drawn to a loricrin vector, classified in Class 435, subclass 320.1, for example.
- II. Claims 5-6, 12, 22, 25, and 26 drawn to a keratin K6 vector, classified in Class 435, subclass 320.1, for example.
- III. Claim 9, drawn to in vivo transduction of cells with a loricrin vector, classified in Class 424, subclass 93B, for example.
- IV. Claim 10, drawn to in vivo transduction of cells with a keratin K6 vector, classified in Class 424, subclass 93B, for example.
- V. Claim 27, drawn to a method of enhancing wound healing with a loricrin vector, classified in Class 424, subclass 93B.
- VI. Claim 28, drawn to a method of enhancing wound healing with a keratin K6 vector, classified in Class 424, subclass 93B.
- VII. Claim 32, drawn to a method of treating skin ulcers with a loricrin vector, classified in Class 424, subclass 93B.
- VIII. Claim 33, drawn to a method of treating skin ulcers with a keratin K6 vector, classified in Class 424, subclass 93B.
- IX. Claim 37, drawn to methods of treatment with a loricrin vector comprising ex vivo transduction and transplantation, classified in Class 424, subclass 93B.
- X. Claim 38, drawn to methods of treatment with a keratin K6 vector comprising ex vivo transduction and transplantation, classified in Class 424, subclass 93B.
- XI. Claim 42, drawn to an in vivo method of treating psoriasis with a loricrin vector, classified in Class 424, subclass 93B.
- XII. Claim 43, drawn to an in vivo method of treating psoriasis with a keratin K6 vector, classified in Class 424, subclass 93B.
- XIII. Claims 47-52, drawn to in vivo methods of treating cancer, classified in Class 424, subclass 93B.
- XIV. Claims 55-57, drawn to in vivo methods of vaccination, classified in Class 424, subclass 93B.
- XV. Claim 58 drawn to a transgenic animal, classified in Class 800, subclass 2.

Claims 7, 8, 13-20 and 53-54 link inventions I and II.

Claims 29-31 link inventions V and VI and will be examined if the required fees are paid for either of these groups.

Claims 34-36 link inventions VII and VIII and will be examined if the required fees are paid for either of these groups.

Claims 39-41 link inventions IX and X and will be examined if the required fees are paid for either of these groups.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US93/03993

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:
(Form PCT/ISA/206 Previously Mailed.)

Please See Extra Sheet.

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.
